Abstract

The linguistic features embedded within business unit information play a crucial role in effectively conveying economic realities, a consideration increasingly recognized in accounting and behavioral finance research. This study endeavors to assess the predictive capacity of companies’ going concern status by integrating structured and unstructured data, while also evaluating the impact of incorporating unstructured variables into traditional data mining models. Spanning from 2012 to 2021, the study encompasses a sample of 540 company years listed on the Tehran Stock Exchange. Tone analysis of auditor reports was conducted using models by Mayew et al. (2015) and Visvanathan (2021), while MAXQDA 20 text analysis software and the Loughran and McDonald (2015) dictionary facilitated data processing. Data analysis and hypothesis testing were performed using the logit regression model and the Vuong test. The findings support the first hypothesis, indicating that the text-based model yields a higher coefficient of determination compared to the data-based approach. Moreover, the second hypothesis reveals a significant discrepancy in the explanatory power between the data-based and integrated text-based models within companies.
1. Introduction

Predicting bankruptcies has been an ongoing research topic in the accounting and financial fields since the late 1960s. Many researchers developed a more robust bankruptcy forecasting model for classification accuracy. While early studies adopted statistical techniques such as multiple resolution analysis (Altman, 1968) and logit analysis (Hamer, 1983; Ohlson, 1980), later studies adopted artificial intelligence approaches such as artificial neural networks (Leshno and Spector, 1996; Odom and Sharda, 1990), decision trees (Shaw and Gentry, 1990), and support vector machines (Shin et al., 2005) as alternative methods for business prediction problems.

A company's bankruptcy is related to the financial situation of the company and the external economic situation. Despite ongoing research on the construction of bankruptcy prediction models in terms of modeling techniques, such as statistical methods and artificial intelligence techniques, studies on using qualitative information for a bankruptcy prediction model have not yet been conducted. Although the use of financial ratios to model bankruptcy prediction is insufficient, research on the development of bankruptcy prediction models mainly uses superior financial ratios as input variables.

Bankruptcy forecasting models based only on financial ratios have several limitations. Accounting information, such as financial ratios, is based on historical data and is usually determined one year before bankruptcy. The bankruptcy prediction model based on financial ratios is a static model (Altman et al., 2010). There is a time interval between the endpoint of the financial statements and the credit rating point. In addition, fiscal ratios do not take into account environmental factors such as external economic situations. Using financial ratios alone may not be sufficient to construct a bankruptcy forecasting model, as they do not reflect the latest information and essentially reflect the company's past internal accounting information. Qualitative data needs to be added to the standard bankruptcy forecasting model to complement the accounting information.

Some past studies have attempted to use nonfinancial information other than internal accounting information, such as the type of business, firm age, and the number of employees (Altman et al., 2010; Grunert et al., 2005; Pervan and Kuvek, 2013), but these efforts continue to merely reflect the nonfinancial internal information of a company due to a lack of technology to obtain and analyze qualitative information produced from an external source. Today, vast amounts of data, including news, blogs, and social networking services, are available online. With the increasing volume of unstructured textual data, big data analysis techniques, particularly text mining, have received considerable attention in academia and industry. However, research on the impact of qualitative information on the forecasting model is still in its infancy and is limited to specific applications such as stock forecasting. Therefore, big data analysis techniques, such as text mining, need to be used for various business forecasting issues, including credit risk assessment.

Bankrupt companies in different stages of bankruptcy have poor financial performance (Campbell et al., 2008). Therefore, the importance of bankruptcy and identifying important and effective factors for it is obvious; even though so far, many researchers have examined the quantitative dimensions of financial reports and information to predict the bankruptcy of companies, this research tried to investigate the effect of the qualitative dimensions of financial reports in predicting bankruptcy. The meaning of tone in financial reports is its positive or negative degree (Mirali et al., 2018). Therefore, using certain methods and tools of text mining, the text's tone is converted into a quantitative state, and then with the selected model, its impact on the desired factors is evaluated (Siano and Wysocki, 2021).
2. Theoretical foundations and research background
2.1 Theoretical

The country faces increasing downward pressure on its economy and an expanding business risk on listed companies. Listed companies, as the solid foundation of the national economy, will experience hazards from multiple perspectives once they face a financial crisis. Therefore, constructing an effective financial crisis early warning model can help beneficiaries predict risks (Zhang et al., 2022). Beneficiaries often look for ways to predict corporate bankruptcy. Therefore, the need for information, especially qualitative information, along with the quantitative information published by the company, has received the attention of beneficiaries more than in the past. Writings in financial reports can focus on persuasiveness. One of the important methods of persuasion is reflecting and repeating certain words of information in the text, which emphasizes the tone of information disclosure (Henry, 2008).

Ideas and thoughts are reflected in the tone of the messages in annual reports (Huang et al., 2014; Yekini et al., 2016). In qualitative texts, positive words are used against negative words to evaluate the text's tone (Kou, 2022). The pessimistic tone of financial statements will cause investors to respond negatively (Feldman et al., 2010; Loughran and McDonald, 2011). Previous research has linked the tone of financial reporting to the company's economic performance and business risk.

Loughran and McDonald (2011) found that words that have a negative tone are more effective and reliable than positive words. This view aligns with Law and Mills’ (2015) psychological research results because humans tend to process more negative than positive information. Another study found that a pessimistic tone influences readers' decisions in a statistically meaningful way (Garcia, 2013).

Researchers used various methods to measure the tone of writing in managers' reports. There are two common approaches to content analysis: the first is based on counting the frequency of specific words (dictionary), and the other is a machine learning classification algorithm method based on assigning an experimental data set to specific categories using a manual coding mechanism (Kashanipoor et al., 2020). In financial research, the methodology based on counting the frequency of specific words is more common and assigns words to different classifications based on predefined rules (Loughran & McDonald, 2011).

In this research, a method based on counting the frequency of specific words was used. There is no consensus in the research literature on text tone word lists, but two lists of words provide the most appropriate classification for use in text analysis (Davis et al., 2015). The first list includes the Loughran and McDonald (2011) dictionary, which is specifically designed to analyze the text of financial and accounting reports, while the second list, the Mohammad and Turney (2013) dictionary, contains the general word list (Bozorg Asl et al., 2021).

This study broadly refers to the information literature of the Annual Reports (Brown and Taker, 2011; Cole and Jones, 2005; Feldman et al., 2010), the bankruptcy prediction literature (Altman, 1968; Beaver et al., 2005; Ohlson, 1980; Shumway, 2001; Zmijewski, 1984), and the literature that studies the auditor's boundaries for its going concern (Carson et al. 2013). This study also contributes to the growing literature on the importance of qualitative disclosure using automated language techniques (Tetlock, 2007; Tetlock et al., 2008; Li, 2010) and, in particular, fills the gap identified by Li (2011) that linguistic analysis may be useful for predicting bankruptcy (Mayew et al., 2015).

Two important research issues raise researchers' interest in giving investors early warning signals through auditor disclosure. Firstly, does the tone of the auditor's report and the business unit's going concern disclosures help predict whether a business will continue to operate? Secondly, to what extent are the outcomes of the first question different from the purely structured data? Discussing the advantages of extending the textual disclosure of financial statements can be aided by the answers to
2.2 Research background

Mayew et al. (2015) examined the role of textual disclosure in a firm's financial statements to predict a firm's ability to continue as a going concern. Using a sample of 262 firms that filed for bankruptcy over the period 1995-2011 and a matched set of control firms, they find that both the management’s opinion and the textual features of management discussion and analysis disclosure together provide significant explanatory power in predicting whether a firm will cease to exist as a going concern. In addition, the ability to predict MD&A disclosure is incremental to financial ratios, market-based variables, and the auditor’s opinion. The study's most important finding is that information in MD&A disclosure is more useful in predicting bankruptcy three years before it occurs. This indicates that MD&A disclosures are more timely than financial ratios, making them a leading indicator of ongoing concern problems.

Jo and Shin (2016) suggest qualitative information should be added to the conventional bankruptcy prediction model to complement accounting information. This study proposes a bankruptcy prediction model for small and medium-sized Korean construction companies using quantitative data such as financial ratios and qualitative data from economic news articles. The performance of the proposed method depends on how well the types of information are converted from qualitative to quantitative information suitable for incorporation into the bankruptcy prediction model. In addition, big data analysis techniques, especially text mining, have been used to process qualitative information. The proposed method involves analyzing keyword-based sentiment analysis using a domain-specific sentiment lexicon to extract sentiment from economic news articles. Experimental results showed that combining qualitative data based on extensive data analysis in the traditional model of bankruptcy forecasting based on accounting information increases forecasting performance. The experimental results showed that incorporating qualitative information based on big data analytics into the traditional bankruptcy prediction model based on accounting information enhances predictive performance. The sentiment variable extracted from economic news articles impacted corporate bankruptcy. In particular, a negative sentiment variable improved the accuracy of predicting corporate bankruptcy because the corporate bankruptcy of construction companies is sensitive to poor economic conditions.

Lopatta et al. (2017) examine whether the language used in 10-K filings reflects a firm's risk of bankruptcy. They use propensity score matching to find healthy matches. Based on a logit model of failing and vital firms, their findings indicate that firms at risk of bankruptcy use significantly more negative words in their 10-K filings than comparable vital companies. They confirm the findings of previous accounting and finance research with their investigation. Beyond the reported financials, 10-K filings contain valuable information. Additionally, they show that 10-Ks filed during a firm's collapse contain a higher proportion of litigious words than healthy businesses. This indicates that the management of failing firms is already dealing with legal issues when reporting financials before bankruptcy. Their results suggest that analysts should include the presentation of financials in their assessment of bankruptcy risk as it contains explanatory and predictive power beyond the financial ratios.

Dey et al. (2017) report that due to the vast amount of textual information generated across various sources on the web, they have begun to combine relevant structured and unstructured data to improve predictions. This study provides a generic deep-learning framework for predictive analysis using structured and unstructured data. They also offer a case study to validate the performance and application of the proposed framework in which LSTM is used to predict the movement direction of these questions.
structured data utilizing events extracted from news articles. Experimental results show that the proposed model outperforms the existing baseline.

Li and Wang (2017) conducted a study in which they compared statistical and machine learning (ML) methods for predicting bankruptcy using Chinese listed companies. They began by selecting the most appropriate indicators using statistical methods. Different indicators may have different characteristics, and not all indicators can be analyzed. The indicators will be more convincing after filtering the data. Unlike previous research methods, researchers used the same sample set to conduct their experiments. The result proves the effectiveness of the machine learning method. Furthermore, with 95.9 percent accuracy, the test outperforms previous studies.

Elsayed and Elshandidy (2020) explored the incremental explanatory power of narrative-related disclosures in predicting corporate failure by creating a comprehensive corporate failure-related lexicon. They found that corporate failure-related narrative disclosures significantly predict firms’ failure up to two years ahead of actual failure. Additionally, they found that a financially distressed firm would become more vulnerable when financial constraints befall, precipitating corporate failure. Various robustness tests assured the credibility of the explanatory ability of corporate failure-related narrative disclosures to predict corporate failure. Collectively, their results showed the feasibility of these narrative-related disclosures in improving the explanatory power of models that predict corporate failure.

According to Gutierrez et al. (2020), investors, regulators, and academics question the usefulness of going concern opinions (GCOs). They assessed whether GCOs provide incremental information relative to other predictors of corporate default. Their measure of incremental information was the additional predictive power that GCOs give to a default model. Utilizing data from 1996 to 2015 found no difference in predictive power between GCOs alone and a default model that includes financial ratios. However, there was an imperfect overlap between GCOs and other predictors. They showed that GCOs increase the predictive power of several models, including ratios, market variables, probability of default estimates, and credit ratings. Using a model that includes ratios and market variables, GCOs increased the number of predicted defaults by 4.4% without increasing Type II errors. Their findings suggested that GCOs summarize a complex set of conditions not captured by other predictors of default.

Lohmann and Ohliger (2020) say the structural and linguistic characteristics of companies’ annual reports (e.g., their length, complexity, and linguistic tone) and the qualitative information they contain (e.g., on the risks a company potentially faces) provide useful insights that can help increase the accuracy of predicting bankruptcy. They use a sample of German companies compiled through propensity score matching to examine what type of textual information allows them to discriminate accurately between companies that are likely to go bankrupt and companies that, although financially distressed, are likely to remain solvent. Their findings provide empirical evidence that both the structural and linguistic characteristics of annual reports and the qualitative information they contain help discriminate between effectively bankrupt companies and companies that are solvent but financially distressed. Furthermore, the study provides empirical evidence that the “management obfuscation hypothesis” is valid because the tone of annual reports produced by bankrupt companies is quantifiably less negative than that of reports produced by companies that, although financially distressed, are likely to remain solvent.

Visvanathan’s (2021) study aligns with the development of Mayew et al.’s (2015) analysis by including deferred tax valuation allowances in their framework. To the extent valuation allowances incorporate managers’ private information about future profitability, valuation allowances are useful in identifying the transitory nature of losses and thus, the going concern status of the firm. Using a sample of firms that filed for bankruptcy over the period 2002–2018, the study shows that increases
Re: valuation allowances are incrementally informative in predicting a firm’s ability to continue as a
going concern after considering management’s textual disclosures, linguistic tone of the MD&A,
auditor’s going concern opinions, financial statement ratios, and market-based variables.

Nießner et al. (2022) conducted a study using qualitative and quantitative criteria to predict
bankruptcy. They concluded that qualitative information from companies’ financial statements
provides useful information that can increase the accuracy of bankruptcy prediction models.

Zhao et al. (2022) conducted a study in which, in addition to financial features, they proposed a
novel framework that combines sentiment tone features extracted from management discussion and
analysis and financial statement notes to predict financial distress. They found that financially
distressed companies were more likely to have weak sentiment. They recommend incorporating
sentiment tone features with financial features, as they contribute to predictive performance
improvements of all models using only financial features. Economic benefits analysis shows that the
proposed framework can correctly identify financially distressed companies.

In the domestic and foreign backgrounds of the research, the bankruptcy and the going concern,
as well as the tone of the auditors’ report, have been investigated. Still, those investigations have not
been carried out simultaneously or in Iran's economic environment with internal data. In this research,
the researchers have conducted research by considering the cases of the going concern, the tone of
the auditors’ report, and the positive and negative words of the reports for the domestic companies.
As a result of this research, the impact of qualitative and textual data along with the quantitative data
of the company, is determined for the interested parties.

The following summarizes the contribution of this paper to the development of the research
literature.

1- The use of qualitative data in addition to quantitative data, improves estimates and forecasts
about the company.

2- It fosters the attitude that qualitative data can be used to predict a company’s going concern,
and it draws more attention to qualitative data in the field of going concern predictions.

3- The present research arouses the interest of researchers to study more in this field and use other
qualitative data.

2.3 Research hypotheses

The two hypotheses of the present study are:

1. Using the text mining approach, the ability to predict the going concern of companies
with/without growth opportunities is greater than the data mining approach.

2. The ability to predict companies with/without growth opportunities using the text mining
approach significantly differs from expecting the going concern using the data mining
approach.

3. Research Methodology

The research is applied in terms of purpose because its results can be used by potential and actual
investors and other groups, and it is correlational because it examines the relationships between
variables using regression analysis. The necessary information on the research literature and
theoretical foundations was obtained from library sources, scientific databases, and national and
foreign articles. Tehran Stock Exchange Organization and Rahavard Novin software database were
utilized to collect research data, reports, and announcements published in the CODAL network. The
MAXQDA software version (2020) and the Loughran and McDonald (2015) dictionary were then
used to process the text analysis section. After extracting the research’s numerical and textual data,
EViews software version 10 was used to test the hypotheses.
3.1 Statistical population and statistical sample
The research statistical population consists of companies listed on the Tehran Stock Exchange, and the study period is from 2012 to 2021. In this study, a statistical sample was performed using the systematic elimination method, Article 141 of the Commercial Code, to select 27 bankrupt companies, and the Q-Tobin ratio to select 27 successful going concern companies. The number of samples used in this research is 540 company years.

3.2 Text mining process
The text mining process involves steps according to Figure 1 to extract data from the document (Kumar and Bhatia, 2013).

![Figure 1. Text mining process](image)

The present study uses the latest updated version of the Loughran and McDonald dictionary (2015), available through the relevant site and contains 354 positive and 2355 negative words. The translation of this dictionary was used to analyze the contents of the auditor's annual report on the activities and general status of the company. For example, with the assistance of content analysis software, the number of positive words (desirable, excellent, and profit) and negative words (unfavorable, weakness, and loss) can be counted in accounting narrations.

The frequency of positive and negative words reflects the tone of the language. We measure the auditor's going concern statement using an index variable (GC_AUD) and if the auditor is unsure of the company's going concern, its value becomes zero; otherwise, it becomes one (Mayew et al., 2015).

The audit reports of the sample companies were extracted from the CODAL site by the researchers for this section. They then entered the Maxqda software to determine the word count within each report. Afterwards, they counted the number of positive and negative words in auditor reports using the Loughran and McDonald dictionaries. For the index variable (GC_AUD), Standard No. 570 of Auditing Standards entitled going concern has been used. A company experiencing going concern difficulties has two instances (although only one is stated in the standard) of signs referred to in this standard that suggest a serious doubt as to whether going concern exists.

3.3 Logit model
The dependent variable in this model is a two-state variable equal to the logarithm of the probability that a particular event (bankruptcy) will happen. The linear probability model as equation 1 can be written in the form of a logistic regression function as equation 2.

\[ Y = b_1 + b_2 X_i \]  \hspace{1cm}  (Equation 1)

\[ \ln \left( \frac{p}{1-p} \right) = b_1 + b_2 X_i + m \]  \hspace{1cm}  (Equation 2)

Therefore, the probability of an event occurring is described in Equation 3.
The maximum probability method is used to estimate Equation 5. We take zero to represent bankruptcy. Suppose the result is greater than 0.5 decimal places (used for the company's equal index of bankruptcy or non-bankruptcy). In that case, the company is less likely to continue as a going concern. Researchers who have used this method include Mayew et al. (2015) and Li and Wang (2017).

3.4 Vuong Z Test

For comparison of the power of two models in a common statistical sample. Considering the coefficient of determination obtained from estimating the two models is necessary. Because the amount of the coefficient of determination determines the model’s power, a model with a higher determination coefficient has more power in explaining and forecasting the dependent variable. However, a test must be carried out to determine whether the difference in the coefficients of determination of the two models is statistically significant. The desired test for comparing the difference between the coefficients of determination of both models was introduced by Vuong and is known as the Vuong Z test (Banimahd et al., 2016).

3.5 Research variables and models

3.5.1 Dependent variable

Bankruptcy: In Iran, Article 141 of a 1968-approved amending bill to a section of the Commercial Law serves as the foundation for bankruptcy. According to this article, the board of directors is required to summon an extraordinary general meeting of shareholders as soon as at least half of the company's capital is lost due to losses so that the issue of the company's survival or liquidation can be discussed and voted on.

3.5.2 Independent variables

Research variables are categorized into both quantitative and qualitative. The quantitative variables are retrieved from the financial statements. The qualitative variables were collected by counting the positive and negative words and dubious phrases from the going concern in the auditor’s report.

In this study, 11 independent variables were used, presented in Table (1) and used in past studies by national and international researchers.

3.6 Research model

According to the studies of Mayow et al. (2015) and Visvanathan (2021), the research model is based on research hypotheses and a data mining approach as equation 4.

\[ Pr(\text{BRUPT}_{t+1}) = \beta_0 + \beta_1 \text{RETA}_t + \beta_2 \text{NETA}_t + \beta_3 \text{EBITTA}_t + \beta_4 \text{CACL}_t + \beta_5 \text{WCTA}_t + \beta_6 \text{TLTA}_t + \beta_7 \text{SALETA}_t + \beta_8 \text{Growth}_t + \theta_t \]

The research model is based on research hypotheses and a text analysis approach, as shown in Equation 5.

\[ Pr(\text{BRUPT}_{t+1}) = \beta_0 + \beta_1 \text{RETA}_t + \beta_2 \text{NETA}_t + \beta_3 \text{EBITTA}_t + \beta_4 \text{CACL}_t + \beta_5 \text{WCTA}_t + \beta_6 \text{TLTA}_t + \beta_7 \text{SALETA}_t + \beta_8 \text{Growth}_t + \beta_9 \text{POSDMA}_t + \beta_{10} \text{NEGMDA}_t + \beta_{11} \text{GC\_AUD}_t + \theta_t \]

4. Analysis of research data and findings

4.1 Unit Root Test

Dummy regression occurs when nonstationary variables are present in the model. The test
presented by Levin et al. (2002) was used to evaluate the significance of the variables. When the time dimensions are large enough, this test is more efficient and powerful than other static tests (Najafzadeh et al., 2024). Table (2) shows the results of a test of the reliability of independent research variables.

If the variables are nonstationary, the co-integration method is used to allow the original values of the variables to be used while ensuring that the regression results are not a dummy. If one of their linear combinations is stationary, a set of values is said to be co-integrated. Therefore, if the explanatory and dependent variable processes co-integrate in a regression model, the possibility of dummy regression is eliminated (Banimahd et al., 2016). The unit root test results in Table (3) show that the distribution of error values in both models in Table (4) is significant. As a result, the linear relationships of the explanatory and dependent variables are co-integrated.

4.2 Results of fitting the regression models of the research

Table (4) compares the results of Logit regression equation estimation to make it easier to compare the explanatory ability of data mining and text mining models for bankruptcy prediction. In the data mining technique, the logit regression model has a coefficient of determination of 62 percent, while the text mining approach has a coefficient of determination of 64 percent.

Symbols ***, ** and * indicate significance levels of 99%, 95% and 90%, respectively.

These coefficients indicate that 3 qualitative variables, positive words, negative words, and the auditor's expression of doubt, along with quantitative model variables, improve the model's explanatory power. Although the variable of positive words is not significant, the variables of negative words and the auditor's expression of doubt with a significance level of 0.1 and 0.01 play an essential role in predicting bankruptcy in the text mining model.

4.3 Results of Vuong Test of research models

The Vuong Z statistic was used to ensure that the incremental explanatory power of the text-mining model compared to the data-mining model in companies with/without growth opportunities was different in Table (5). Consequently, the incremental explanatory power of a model with a bigger $R^2$ is greater. The text mining model has more explaining power than the data mining model in enterprises with and without growth opportunities. Overall, these results show that the increasing explanatory power of the text mining model in companies with and without growth opportunities differs significantly from the data mining model.

5. Conclusions and suggestions

Text mining is obtaining high-quality information from unstructured or semi-structured texts or data (Hearst, 2003). Accordingly, in modern accounting and behavioral finance, particular attention has been paid to the relationship between the linguistic characteristics of enterprises' annual reports and their behavior and economic results (Davis et al., 2015; Huang et al., 2014). In recent years, the study of linguistic features of financial reporting in experimental accounting research has been prompted by the variety of disclosable issues, the diversity of different industries of international companies, and the existence of various institutions that formulate accounting standards at the global level. Although numerous studies have been conducted on bankruptcy and the influence of different...
factors in its determination, the tone of the financial reports as a linguistic characteristic of the company's financial reports was not considered. It was found that adding textual variables to data mining models with the presence of company size improves the coefficient of determination of logit regression models, according to the results obtained from testing the first hypothesis of the research in Table (4). Moreover, the predictive power of text mining is greater, as shown in Table (5), and the difference is significant.

Finally, the search hypotheses are confirmed based on the results obtained and the corresponding coefficients. Furthermore, the findings of this study are consistent with those of Mayow et al. (2015), Elsayed et al. (2020), Lohmann and Ohliger (2020), Viswanathan (2021), and Nießner et al. (2022). It is suggested that the Auditing Organization, Tehran Stock Exchange and Securities Organization design a specific framework that includes compiling explanatory reports with a specific lexicon for both formulating new laws and amending previous cases with the knowledge of how auditors manage perception. In addition, auditing firms are urged to take into account the tone of financial statements when assessing the level of risk to the client company, the planning of operations, and the volume of audit tests, among other factors.

Ultimately, it is suggested that the following be investigated in future research:
1. Comparing the predictive power and ongoing concern of companies using text mining and data mining approaches with qualitative variables of the activity report of the board of directors
2. The effect of financial reporting tone on the comparability of financial statements.
3. Further, variables in the current study were examined over 10 years and in a sample of 54 companies, which suggests a longer period with a much larger sample can be useful.

In the research process, a set of conditions and cases are out of control but can potentially affect the results. It is necessary to examine the results of the research, taking into account the existing limitations. The limitations of this study were as follows:
1. Lack of Persian dictionaries that can be used as a standard tool to measure writing tone in financial research. Thus, due to the use of English dictionaries in translation and the linguistic differences, the reliability of research tools would increase if there were a standard dictionary in Persian.
2. As the word file of the auditor’s reports was unavailable, calculating the financial reporting tone index was very challenging.
3. According to all the text descriptions in the report, the research results are obtained in the tone inferred. Nonetheless, the tone inferred by the investor from a fraction of the text differs from the tone inferred from the entire text because there is no guarantee of an equal distribution of positive, negative, or neutral words in all paragraphs.
